Stochastic Gradient Descent (SGD)

**Gradient Flow** 

## Gradient Flow

Gradient flow is a non-stochastic (deterministic) model of stochastic gradient descent (SGD).

Gradient flow is defined by the total gradient differential equation

$$\frac{d\Phi}{dt} = -g(\Phi) \qquad g(\Phi) = \nabla_{\Phi} E_{(x,y)\sim \text{Train}} \mathcal{L}(\Phi, x, y)$$

We let  $\Phi(t)$  be the solution to this differential equation satisfying  $\Phi(0) = \Phi_{\text{init}}$ .

## **Gradient Flow**

$$\frac{d\Phi}{dt} = -g(\Phi)$$

For small values of  $\Delta t$  this differential equation can be approximated by

$$\Delta \Phi = -g(\Phi)\Delta t$$

## Time as the Sum of the Learning Rates

Consider the update.

$$\Delta \Phi = -g\Delta t$$

Here  $\Delta t$  has both a natural interpretation as time in a numerical simulation of the flow differential equation.

But it also has a natural interpretation as a learning rate.

This leads to interpreting the sum of the learning rates as "time" in SGD.

### Gradient Flow and SGD

Consider a sequence of model parameters  $\Phi_1, \ldots, \Phi_N$  produced by SGD with

$$\Phi_{i+1} = \Phi_i - \eta \hat{g}_i$$

and where  $\hat{g}_i$  is the gradient of the *i*th randomly selected training point.

Take  $\eta \to 0$  and  $N \to \infty$  using  $N = t/\eta$ . We will show that in this limit for SGD we have that  $\Phi_N$  converges to  $\Phi(t)$  as defined by gradient flow.

### Gradient Flow and SGD

For  $\Phi_{i+1} = \Phi_i - \eta \hat{g}_i$  we divide  $\Phi_1, \ldots, \Phi_N$  into  $\sqrt{N}$  blocks.  $(\Phi_1, \ldots, \Phi_{\sqrt{N}}) (\Phi_{\sqrt{N+1}}, \ldots, \Phi_{2\sqrt{N}}) \cdots (\Phi_{T-\sqrt{N+1}}, \ldots, \Phi_N)$ 

For 
$$\eta \to 0$$
 and  $N = t/\eta$  we have  $\eta \sqrt{N} \to 0$  which implies  
 $\Phi_{\sqrt{N}} \sim \Phi_0 - \eta \sqrt{N}g$ 

where g is the average (non-stochastic) gradient.

Since the gradients within each block become non-stochastic, we are back to gradient flow.
